

Celestial Sleuths Solve Another Munch Mystery

By the Editors of *Sky & Telescope*

For a century art historians have wondered why Edvard Munch chose not to depict a celestial reflection in this famous painting, *Girls on the Pier*. Now the mystery is solved. © 2004 The Munch Museum / The Munch-Ellingsen Group / Artists Rights Society, NY.

March 20, 2006 | Edvard Munch (1863–1944) is best known today for his iconic painting *The Scream*, but a century ago the Norwegian artist's fame was firmly tied to his idyllic masterwork *Girls on the Pier*.

Despite its beloved status, two elements of the painting have puzzled admirers over the years: The yellow orb that Munch placed in the sky — which different authorities have conflictingly identified as the Sun and the Moon — and the mysterious absence of this orb from a mirror image of the scene reflected in the waters of the still Norwegian fjord.

Through a combination of forensic astronomy and old-fashioned historical research, Texas State professors Don Olson and Russell Doescher, along with undergraduate Beatrice Robertson, have conclusively identified the disk as the setting Moon. Additionally, the researchers hit upon a simple physical explanation accounting for the Moon's odd absence from the reflection below. The team's complete findings are published in the May 2006 issue of *Sky & Telescope*, now in the mail to subscribers.

Munch created at least 20 variations of the scene from *Girls on the Pier*, of which the version in the National Gallery in Oslo, Norway,

is believed to be the first and dated to either 1899 or 1901. To test their theories, the Texas State researchers traveled to Åsgårdstrand, a summer resort in Norway where Munch lived and painted during this time. There, on the shore of the fjord, they found the distinctive houses, fence, and trees from Munch's painting almost exactly as depicted more than a century ago.

"Åsgårdstrand is well south of the Arctic Circle, so we knew that the yellow disk couldn't be the Midnight Sun," said Olson, who previously applied his astronomical sleuthing skills to connect the blood-red sky in *The Scream* to volcanic twilights following the great 1883 eruption of Krakatoa ([S&T: February 2004, page 28](#)). "At Åsgårdstrand, near the summer solstice, they have what are called 'light nights,' and what that means is that there's a midnight twilight — it just doesn't get dark."

The light summer nights meant that the yellow object could be either the Sun or the Moon while still allowing for the bright colors and details of Munch's painting. After determining Munch's vantage point using old photographs of the harbor and topographic calculations, the researchers set about establishing the paths of the Sun and Moon across the Norwegian summer sky. The results were clear.

"The summer sunset would be way over to the north of the pier — far to the artist's right, whereas summer full Moons would run low in the sky and set exactly where he shows it," Olson said. "That tells us that the yellow disk must be the full Moon."

After the field work in Åsgårdstrand, the team tracked down several obscure letters written in 1902 by Munch calling the painting *Summer Night*, further evidence supporting the Texas State researchers' conclusion that the painting is a nighttime scene, and that the disk is indeed the Moon.

With the yellow disk in the painting firmly established as the Moon, the researchers turned their attention to the second, more perplexing question: Why isn't it reflected in the water?

Over the years, various scholars have explained the absent reflection as artistic license, symbolic of failing memory, or key to the scene's emotional balance. Olson turned to a book by the late Marcel Minnaert, a pioneer in the field of atmospheric optics. In Minnaert's book he found not only an explanation for the phenomenon, but also a diagram that matched the circumstances of Munch's painting with startling accuracy.

"When we saw the diagram of the same phenomenon that's depicted in Munch's painting, it was almost eerie," Olson recalled. "The key point is that your eye is approximately 11 feet above the water level — the reflective surface. Light can come directly from the Moon to the observer, whose eye is above the pier, but the light that tries to come from the Moon to reflect off the water is blocked by the house."

"This is entirely caused by the fact the observer's eye is above the water level. If you could put your eye right at the water level, you'd see the same thing above and below. But you're offset, and this causes an asymmetry," he said. "We're not the first people to discover this phenomenon of optics — it's well known. But we are the first people to apply it to Munch's painting. It's a physical explanation for the missing reflection, not a psychological or symbolic one."

The team's calculations explain several subtle changes in perspective of the roof line and chimney of the house reflected in the fjord as well, Olson said, leaving the researchers impressed by the artist's accuracy and detail in depicting the northern summer night and the reflection in the water.
