

Researchers Speculate How the First Stars in the Universe Came into Existence

Posted by [Guy Pirro](#) on 7/31/2008 8:05 PM

This is an artist's concept of the first stars in the Universe firing-up. The first primordial stars began as tiny seeds that grew rapidly into stars one hundred times the mass of our own Sun. Swirling clouds of hydrogen and helium gasses are illuminated by the first starlight to shine in the Universe. Over time, exploding supernovae eject into space heavier elements that will eventually be incorporated into new stars and planets. (Image Credit: NASA/WMAP Science Team)

further investigation into the star formation process. The question of how the first stars evolved is so important because their formations and eventual explosions provided the seeds for subsequent stars to come into being.

According to the researchers' simulation, gravity acted on minute density variations in matter, gases, and the mysterious "dark matter" of the universe after the Big Bang in order to form this early stage of a star — a protostar with a mass of just 1% of our sun. The simulation reveals how pre-stellar gases would have actually evolved under the simpler physics of the early universe to form this protostar. Yoshida's simulation also shows that the protostar would likely evolve into a massive star capable of synthesizing heavy elements, not just in later generations of stars, but soon after the Big Bang.

"This general picture of star formation, and the ability to compare how stellar objects form in different time periods and regions of the universe, will eventually allow investigation into the origins of life and planets," said Lars Hernquist, a professor of astronomy at Harvard University. "The abundance of elements in the universe has increased as stars have accumulated," he says, "and the formation and destruction of stars continues to spread these elements further across the universe. So when you think about it, all of the elements in our bodies originally formed from nuclear reactions in the centers of stars, long ago."

Researchers believe that our universe began with the Big Bang about 13 billion years ago, and that soon after that event, the gravitational effects of dark matter began to influence wayward gases. How the first stars formed from this dark matter and gas has been a burning question for years. Now a state-of-the-art computer simulation offers the most detailed picture yet of how these first stars in the universe came into existence, researchers say.

The composition of the early universe was quite different from that of today, and the physics that governed the early universe were also somewhat simpler. Naoki Yoshida and colleagues in Japan and the United States incorporated these conditions of the early universe, sometimes referred to as the "cosmic dark ages," to simulate the formation of an astronomical object that would eventually shine its light into this darkness.

The result is a detailed description of the formation of a protostar — the early stage of a massive primordial star of our universe — and the researchers' computer simulation, which has been called a "cosmic Rosetta Stone," sets the bar for

Their simulation of the birth of a protostar in the early universe signifies a key step toward the ambitious goal of piecing together the formation of an entire primordial star and of predicting the mass and properties of these first stars of the universe. More powerful computers, more physical data, and an even larger range will be needed for further calculations and simulations, but these researchers hope to eventually extend this simulation to the point of nuclear reaction initiation — when a stellar object becomes a true star.

"Dr. Yoshida has taken the study of primordial star formation to a new level with this simulation, but it still gets us only to the halfway point towards our final goal. It is like laying the foundation of a skyscraper," said Volker Bromm, assistant professor of astronomy at the University of Texas, Austin. "We must continue our studies in this area to understand how the initially tiny protostar grows, layer by layer, to eventually form a massive star. But here, the physics become much more complicated and even more computational resources are needed."
